Abstract: Surgical resection is a mainstay of brain tumor treatments. However, the completed excision of malignant brain tumor is challenged by its infiltration nature. Contrast enhanced magnetic resonance imaging (MRI) is widely used for defining brain tumor in clinic. However its ability for tumor visualization is hindered by the transient circulation lifetime, non-targeting specificity and poor blood brain barrier (BBB) permeability of the commercially available MR contrast agents. In this work, we developed a two-order targeted nanoprobe in which MR/optical imaging reporters, tumor vasculature targeted cyclic [RGDyK] peptides and BBB permeable Angiopep-2 peptides are labeled on PAMAM-G5 dendrimer. This nanoprobe is supposed to firstly target the $\alpha_V\beta_3$ integrin on tumor vasculatures. Increased local concentration of nanoprobe facilitates the association between BBB permeable peptides and the low-density lipoprotein receptor-related protein (LRP) receptors on the vascular endothelial cells, which further accelerates BBB transverse of the nanoprobe *via* LRP receptor mediated endocytosis. The nanoprobes that have penetrated BBB secondly

target the brain tumor because both $\alpha_V\beta_3$ integrin and LRP receptor are highly expressed on the tumor cells. *In vivo* imaging studies demonstrated that this nanoprobe not only efficiently crossed intact BBB in normal mice, but also precisely delineated the boundary of orthotropic U87MG human glioblastoma xenograft with high target to background signal ratio. Overall, this two-order targeted nanoprobe holds the promise to non-invasively visualize brain tumors with uncompromised BBB and provides the possibility for the real-time optical image-guided brain tumor resection during surgery.

Keywords: Brain tumor, Nanoprobe, Multimodal imaging, Blood Brain Barrier, Two-order targeting

Abbreviations: GBM, glioblastoma multiforme; AA, anaplastic astrocytoma; MRI, magnetic resonance imaging; CA, contrast agent; Gd, gadolinium; NIR, near-infrared; EPR, enhanced permeability and retention; BCEC, brain capillary endothelial cell; Tf, transferrin; BBB, blood brain barrier; LRP, low-density lipoprotein receptor-related protein; PDI, polydispersity index; BTV, brain tumor vasculature, RAP, low-density lipoprotein receptor-associated protein; PI, post-injection; T/N ratio, tumor to normal tissue ratio; MTT, (3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide; IC_{50}: the half maximal inhibitory concentration.

Even the advances in tumor diagnosis and therapy have improved the survival of cancer patients, malignant brain tumors continue to be the cause of a disproportionate morbidity and mortality.[1] For example, the median survival of patients suffering aggressive glioblastoma multiforme (GBM) is about 15 months and the anaplastic astrocytoma (AA) is 2–3 years.[1-2] The standard therapy for brain tumors involves surgical resection followed radiotherapy or/and chemotherapy.[3] However, malignant brain tumors are hard to eliminate completely due to their heterogeneous and infiltrative nature, which leads to the precise resection of tumor from the surrounding healthy brain tissue difficult during the surgery.[4] Magnetic resonance imaging (MRI) is a standard neuroimaging technique for pre-operative localization of brain tumor.[5,6] Gadolinium (Gd^{3+}) based MR contrast agents (CAs) such as Gd^{3+}-DTPA (Magnevist®) are widely used to define tumor margin in clinic.[7] These small molecular MR CAs diffuse into the tumor bed where the blood brain barrier (BBB) is disrupted and lead to MR signal enhancement. Unfortunately, the Gd approach is limited in that about 10% GBM and 30% AA don't show any MR signal enhancement due to uncompromised BBB.[8] Moreover, the transient circulation lifetime and non-targeting specificity of these CAs further hinder their application. Therefore, the probes with BBB permeability, optimized circulation lifetime and high targeting specificity are needed.

Nanoprobes demonstrate advantages in tumor imaging including the tunable circulation lifetime,[9] enhanced permeability and retention (EPR) effect that up-regulates intratumoral delivery due to the high permeability of tumor vasculatures[10–11] and multivalent effect that increases receptor targeting specificity by labeling multiple ligands on a single

nanoparticle.[12] Even previous works unambiguously showed the capability of nanoprobes to visualize subcutaneous tumor xenografts *in vivo*,[13,14] the performance of these nanoprobes for brain tumor imaging is far from satisfaction because BBB prevents the intracerebral delivery of almost all exogenous macromolecules.[15] Receptor-mediated transcytosis is a natural pathway through which the endogeneous proteins pass the BBB.[16] Receptors presented on the brain capillary endothelial cells (BCECs) play active role in mediating the intracerebral delivery of their corresponding ligands. Taking advantage of this property, the receptor targeting ligands such as transferrin (Tf),[17] rabies virus glycoprotein peptide (RVG29)[18] and snake neurotoxin candoxin peptide (CDX)[19] were functionalized into the nanoparticles to up-regulate their BBB permeability. Recently, Jia *et al*. reported a drug delivery vector in which two different receptor-targeting ligands: Tf and wheat germ agglutinin (WGA) were conjugated.[20] The improved therapeutic efficacy of this nanoparticle to brain tumor was explained by the increased intratumoral delivery of the chemotherapeutics resulted from the synergistic effect of Tf associated receptor-mediated transcytosis and WGA associated adsorptive endocytosis. Above work demonstrated the feasibility to enhance the brain tumor uptake of nanoparticles by increasing their BBB traverse efficiency.

In this work, we developed a novel two-order targeted imaging strategy, which visualizes brain tumor by up-regulating the BBB permeability and receptor targeting specificity of nanoprobes (Fig. 1A). In this strategy, a nanoparticle labeled with MR/optical imaging reporters, tumor vasculature targeting cyclic [RGDyK] peptides and BBB permeable

Angiopep-2 peptides was prepared. In the first step, this nanoprobe targets the tumor neovasculatures that are abundant in tumor periphery. The increased local concentration of nanoprobe facilitates the association between BBB permeable peptide and corresponding receptor on the vascular endothelial cells, which accelerates BBB transverse of the nanoprobe *via* the receptor mediated transcytosis. In the second step, the nanoprobes that have penetrated BBB target the brain tumor directly because the corresponding receptors are also highly expressed on tumor cells. This two-order targeting strategy realizes the specific intratumoral delivery of imaging probes without disturbing normal function of the BBB. $\alpha_V\beta_3$ integrin as a receptor for extracellular matrix proteins is over-expressed on the activated endothelial cells of tumor neovasculatures, certain tumor cells, but not the normal vasculatures.[21] Therefore, $\alpha_V\beta_3$ integrin presents an ideal molecular target for tumor diagnosis and therapy.[22] Cyclic arginine-glycine-aspartic (RGD) tripeptide sequence shows higher binding affinity to $\alpha_V\beta_3$ integrin (subnanomolar level)[23] and c[RGDyK] peptide was chosen as the tumor vasculature targeting ligand here due to its convenience to be labeled covalently on nanoparticles. Meanwhile, low-density lipoprotein receptor-related protein (LRP) plays an active role in mediating the transport of numerous ligands across BBB including lipoproteins, protease/protease inhibitor complexes and extracellular matrix proteins.[24,25] Angiopep-2, a 19 amino acid peptide derived from the common peptidic sequence of the LRP protein ligands, demonstrates a much higher BBB transcytosis efficacy than transferrin and its mother molecule aprotinin.[26,27] Importantly, LRP receptors not only express in BCECs, but also in many types of glioblastomas.[28] Therefore, angiopep-2 was chosen as the BBB permeable ligand functionalized on the nanoprobe.

Like a “Great Wall” in brain, BBB protects the brain microenvironment from fluctuations in concentrations of ions, metabolites, unwanted materials in the circulation system and keeps the brain working under a perfect condition.[29] However, this defense proves to be a nightmare during the treatment of brain tumor or other neurological diseases.[30,31] Therefore, the intracerebral delivery of the imaging/therapeutic agents by circumventing BBB is a challenging but meaningful task. The objective of this work is to evaluate a novel imaging strategy to non-invasively visualize the brain tumor with high sensitivity and target to background signal ratio without the compromise to BBB.

Result:

The Receptor Expression Level on Targeted Cells. High expression of both $\alpha_V\beta_3$ integrin and LRP receptor in BCECs and brain cancer cells is a prerequisite for the success of the two-order targeted imaging strategy. Receptor expression levels in the targeted cells were immunoblotted by LRP1 and β_3 antibodies respectively. As shown in Fig. 1B, BCECs demonstrated the immunoreactive bands at 85 and 110 kDa, the anticipated molecular weights of LRP receptor and $\alpha_V\beta_3$ integrin. The receptor expression levels were also tested in three human cancer cell lines including glioblastoma U87MG cells, prostate PC3 cells and breast MDA-MB-231 cells. U87MG cells demonstrated the highest expression level of LRP receptor. Densitometry studies showed that LRP receptor levels in U87MG and BCECs were much higher than that in PC3 and MDA-MB-231 cells. Meanwhile, U87MG and BCEC cells showed a comparable β_3 integrin expression level, but this receptor was not found in PC3 and MDA-MB-231 cells.

Design, Synthesis and Characterization of the Nanoprobes. The fifth generation (G5) PAMAM dendrimer was chosen as a platform of the nanoprobes due to its globular architecture, identical molecular weight, optimized circulation lifetime and well-defined reactive groups on the particle surface.[32,33] Near-infrared (NIR) fluorophore Cy5.5 was labeled on the dendrimer because tissue absorption and autofluorescence in this region (650–900 nm) are low, which allows the NIR light to penetrate into deep tissue.[34] The conjugated rhodamine was used to track the nanoprobes in either cells or excised tissues because Cy5.5 cannot be excited well under a conventional fluorescent microscope. Gd^{3+}-DOTA was chosen as the MR CAs functionalized on the nanoprobe due to its high thermodynamic stability and kinetic inertness.[35] Both angiopep-2 and c[RGDyK] peptides were labeled on the dendrimer through a PEG linker. This extended PEG linker not only improves the biocompatibility of the nanoprobe, but also minimizes the steric hindrance of the hyper-branched polymer to the targeting specificity of ligands.

The aiming nanoprobe **Den-RGD-Angio** labeled with both angiopep-2 and c[RGDyK] peptides, control nanoprobes **Den-RGD** modified with only c[RGDyK] peptides were synthesized in Fig. 2A. Briefly, treatment of maleimide (Mal) and N-hydroxysuccinimidyl (NHS) ester functionalized PEG derivative Mal-PEG^{2k}-NHS with c[RGDyK] offered compound **1**, which further reacted with dendrimer to give **2**. The conjugation of NHS esters of rhodamine, Cy5.5 and DOTA with **2** respectively gave **3** that then complexed with Gd^{3+} ions to produce **Den-RGD**. The reaction between bis-functionalized PEG derivative

Mal-PEG^{2k}-NH_2 and N-succinimidyl 3-(2-pyridyldithio) propionate (SPDP) offered **4**. The condensation between **4** and **2** resulted in **5**. The conjugation of NHS esters of rhodamine, Cy5.5 and DOTA with **5** subsequently gave **6** that further reacted with peptide TFFYGGSRGKRNNFKTEEYC followed a complexation with Gd^{3+} yielding **Den-RGD-Angio**. The detail synthetic procedure of **Den-RGD** and **Den-RGD-Angio** was described in supporting information. Meanwhile, synthesis of control nanoprobes **Den-Angio** labeled with angiopep-2 peptides and **Den-PEG** without any targeting ligand was described in our previous work.[36] The chemical structures of four nanoprobes were presented in Fig. 2B.

The physical parameters of those nanoprobes were listed in Table 1. The hydrodynamic diameter of **Den-RGD-Angio** was determined as 15.6 nm, which was slightly larger than that of control nanoprobes. The polydispersity index (PDI) of all nanoprobes kept below 0.3 and every nanoprobe migrated as a single band in the fluorescence images of the resolved sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) (Fig. S1). All nanoprobes showed the positive charges in the physiological pH, but the values were much lower than that of unconjugated G5 dendrimer (Fig. S2). The molar ratio of angiopep-2/c[RGDyK]/Gd^{3+}-DOTA/dendrimer in **Den-RGD-Angio** was measured as 5/6/54/1. The molecular weights (MWs) of these nanoprobes were determined by MALDI-TOF mass spectra (Fig. S3). All nanoprobes demonstrated similar longitudinal relaxivity r_{1p} values in a range of 7.1–7.4 mM^{-1} s^{-1}/Gd^{3+}.

Cytotoxicity and Cellular Uptake Studies. The cytotoxicities of the nanoprobes were

evaluated in U87MG cells *via* MTT assay. As shown in Fig. S4, all nanoprobes demonstrated much lower cytotoxicities compared to the unmodified dendrimer. The IC_{50} values of the nanoprobes were measured in a range of 6–30 μM, which were at least 20 times higher than that of unmodified dendrimer (0.3 μM). *In vitro* confocal fluorescence microscopic imaging demonstrated the attachment of **Den-RGD-Angio** on the cell membrane when the U87MG cells were treated with this nanoprobe for 15 min at 4 ºC (Fig. 3A). Above experiment verifies the ligand/receptor association because the active cellular uptake was minimized under low temperature. In order to evaluate the receptor targeting specificity of **Den-RGD-Angio**, U87MG cells were treated with this nanoprobe in the presence of the low-density lipoprotein receptor-associated protein (RAP) that was utilized as a receptor competitor of LRP receptor and free c[RGDyK] peptide that was utilized as a competitor of $\alpha_V\beta_3$ integrin. While the uptake of **Den-RGD-Angio** did not change upon the treatment with c[RGDyK], no cellular uptake of this nanoprobe was monitored after the pre-incubation of RAP (Fig. 3A). Above results indicated that LRP receptor played the predominated role in the cellular uptake of **Den-RGD-Angio**. After 24 h incubation at 37 ºC, while **Den-RGD-Angio** distributed in whole cytoplasm as vesicular structures, **Den-PEG** was sporadically located at the perinuclear areas (Fig. 3B). Internalizations of **Den-RGD** and **Den-Angio** were evident, but their uptakes were obviously lower than that of **Den-RGD-Angio**. Interestingly, quite different time-dependent internalization patterns of the nanoprobes were observed by flow cytometry (Fig. 3C and Fig. S5). **Den-RGD-Angio** and **Den-Angio** showed their fastest uptakes in the first 15 min. The initial uptake rates of **Den-PEG** and **Den-RGD** were much lower than that of **Den-RGD-Angio**, however, a

sustained internalization of **Den-RGD** was observed. Average cellular fluorescence intensity was quantified with an order of **Den-RGD-Angio** > **Den-Angio** > **Den-RGD** > **Den-PEG** during the whole treatment procedure and the cellular uptake of **Den-RGD-Angio** was found significantly higher than those of **Den-Angio** and **Den-PEG** ($P < 0.001$, n = 4) at 15 min, 1 h and 24 h post treatment (Fig. 3D).

***In Vivo* Imaging Studies.** Dynamic T1-weighted MR images showed the prolonged circulation lifetime of **Den-RGD-Angio** because the MR signal enhancement in intracerebral vasculatures such as superior sagittal sinus and straight sinus lasted for more than 2 h (upper panel of Fig. 4A). BBB permeability of **Den-RGD-Angio** was obvious with the evidence of platelet-like hyperintense regions (positive contrast) in cortex at 24 h post injection (PI). Average MR signal in the cortex increased 7.5% (n = 4) compared to its pre-contrast values at 24 PI. BBB permeability of **Den-RGD-Angio** was further verified by the *in vivo* NIR fluorescence imaging (Fig. 4C). The merged X-ray/optical image of enlarged mouse head clearly indicated the location of this nanoprobe inside the skull that was delineated by X-ray image. In contrast, the intracranial NIR fluorescence of **Den-PEG** was remaining at the background level during the whole imaging process.

T1-weighted MR imaging demonstrated the feasibility of **Den-RGD-Angio** to visualize the orthotropic U87MG glioblastoma xenograft *in vivo*. A heterogeneous MR signal enhancement in tumor was observed as fast as 10 min PI. The tumor boundary was more evident at 2 h PI and it correlated well with the H&E stained histological tissue section of the

identical brain tissues (low panel, Fig. 4A). Fig. 4B showed that the MR signal intensity ratio between the tumor and surrounding normal neurological tissue (T/N ratio) kept increasing after **Den-RGD-Angio** administration and reached its maximum value of 1.52 at 24 h PI. **Den-RGD-Angio** also performed the highest NIR fluorescence associated T/N ratio in all nanoprobes and its maximal value of 1.49 was measured at 24 h PI (Fig. 4C–D).

Bio-distribution and *Ex Vivo* Imaging Studies. *Ex vivo* NIR fluorescence images of the excised normal mouse brain unambiguously demonstrated the accumulation of **Den-RGD-Angio** in the cortex of normal brain (Fig. 5A). The average NIR fluorescence of **Den-RGD-Angio** in the whole excised brain was measured as 17% (n = 3) higher than that of **Den-PEG** (Fig. S6A). Microscopic fluorescent images of normal mouse brain sections showed that **Den-RGD-Angio** and **Den-Angio** penetrated the brain capillaries and located in the cortex parenchyma at 24 h PI (Fig. S6B). Whereas, no detectable intracerebral deliveries of **Den-RGD** and **Den-PEG** were found. **Den-RGD-Angio** also showed the highest T/N ratio in the excised brain bearing U87MG tumor xenograft (Fig. 5B) and the data was measured as 5.6 at 24 h PI, which was much higher than the control nanoprobes (n = 3, Fig. S6C). The bio-distribution data expressed as a percentage of injected dose/gram of tissue (%ID/g) were evaluated in U87MG tumor bearing mice at 24 h PI of nanoprobes labeled with radioactive ^{125}Iodide (Fig. 5C). All nanoprobes mainly located in the liver, spleen and kidney. The intratumoral uptake of **Den-RGD-Angio** ($0.36 \pm 0.05\%$ ID g^{-1}) was about 1.4, 1.7 and 2.6 times higher than that of **Den-RGD**, **Den-Angio** and **Den-PEG** respectively. Fig. 5D demonstrated the white light and corresponding radioautographic

images of the tumor bearing brain sections at 24 h PI of the ^{125}I labeled nanoprobes. The intratumoral delivery of nanoprobes was evident with the high radioactivity (displayed as deep color) shown in the tumor area. **Den-RGD-Angio** gave the highest T/N ratio that was measured as 1.41 at 24 h PI.

Microscopic Immunofluorescence Imaging Studies. Fig. 6A demonstrated the fluorescence microscopic images of tumor bearing brain sections at 24 h PI of nanoprobe. In contrast to the concentrated distribution of **Den-RGD-Angio** in entire tumor, **Den-PEG** was only scatteredly located at the tumor boundary that can be defined by the fluorescence images of nucleus stained by DAPI. The enlarged images indicated that **Den-RGD-Angio** was internalized into the cancer cells and distributed as the vascular structures at the perinucleus areas. The intratumoral deliveries of **Den-RGD** and **Den-Angio** were lower than that of **Den-RGD-Angio** but significantly higher than that of **Den-PEG**. Fig. 6B indicated the average cellular fluorescence intensities in the tumor and normal cells at 24 h PI of nanoprobe. Compared to **Den-PEG**, the average fluorescence intensities in normal neurological cells increased 1.2, 1.6 and 1.7 (15 slices analyzed from three tumors) times for **Den-RGD**, **Den-Angio** and **Den-RGD-Angio** respectively. Remarkably, the average fluorescence intensities of **Den-RGD**, **Den-Angio** and **Den-RGD-Angio** in brain tumor cells were measured as 2.8, 2.7 and 4.5 times higher than that of **Den-PEG**.

This two-order targeted imaging of **Den-RGD-Angio** was further investigated by the microscopic immunofluorescence imaging. Firstly, the targeting specificity of

Den-RGD-Angio to $\alpha_V\beta_3$ integrin was assessed at 2 and 24 h PI of the nanoprobe. The β_3 integrin was predominately located at the tumor margin with high vasculature density (Fig. 6C). The rhodamine fluorescence of **Den-RGD-Angio** colocalized well with the β_3 integrin immunofluorescence at 2 h PI. However, the colocalization coefficient between the β_3 integrin and nanoprobe decreased from 0.74 at 2 h PI to 0.26 (18 slices analyzed from three tumors) at 24 h PI due to the continued uptake of this nanoprobe in the tumor core area (Fig. 6D). The targeting specificity of nanoprobe to the LRP receptors was also studied. The LRP receptors are heterogeneously located in the brain tumor and the colocalization coefficient between LRP receptor and **Den-RGD-Angio** was determined as high as 0.86 at 2 h PI (Fig. 6D). Interestingly, the immunofluorescence of LRP receptor in the tumor core area disappeared and the colocalization coefficient reduced to 0.07 (18 slices analyzed from three tumors) at 24 PI.

Discussion:

Poor BBB permeability of the imaging/therapeutic agents is a bottleneck that limits the successful brain tumor diagnosis and treatment. In proof-of-principle, we put forward a novel two-order targeted nanoprobe to non-invasively image the brain tumor by circumventing BBB *in vivo*. The up-regulated BBB traversing efficacy of this nanoprobe results from: (1) multivalent effect that boosts the avidity to the targeted receptor on brain tumor vasculatures. For example, Josephson *et al*. reported the binding affinity of the nanoparticle modified with twenty c[RGDfK] peptides was 71 times higher compared to that of the free peptide;[37] (2) high local ligand concentration effect that up-regulates the receptor

mediated transcytosis. DeSimone *et al* reported that the cellular uptake of the PRINT nanoparticle was proportional to the density of the labeled Tf.[38] Therefore, a combination of the multivalent effect and the high local ligand concentration effect can remarkably increase the BBB permeability of nanoprobes.

Higher permeability of tumor vasculature provided a natural selection process to allow the nanoparticles to extravasate into the tumor interstitium but not the normal tissues.[39] However, brain tumor vasculature (BTV) retains some features of the BBB such as tight interendothelial junctions and transendothelial channels.[15] For example, Sarin *et al*. found the upper limit of the pore size in BTV would be less than 20 nm in diameter,[33] which is much smaller than that of extracranial tumors up to 1–5 μm.[39] Furthermore, the nanoprobes smaller than 5 nm are also not suitable for brain tumor imaging because their fast excretion *via* renal filtration results in their transient residence in blood pool.[40] In this work, the diameters of the nanoprobes are in a range of 11–16 nm that are small enough to traverse BTV but bigger enough to achieve the prolonged circulation lifetime. The reduced cytotoxicity of the nanoprobes compared to the unmodified dendrimer can be explained by their lower positive charges that reduce the non-specific accumulation of nanoprobe in the normal tissues.[41] However, the residue positive charge of nanoprobes would potentially facilitate their intratumoral uptake *via* the electrostatic interaction between the cationic nanoprobe and the negative charged sulfated proteoglycans over-expressed on the cancer cells.[42] High sensitivity of NIR fluorescence imaging can compensate the inherent shortage of MRI by using the multimodal nanoprobes, and it is promising to generate the images with

high spatially resolution as well as the sensitivity. Meanwhile, due to the numerous MR chelators labeled on the nanoprobe, the overall relaxivity of the nanoprobe can be as high as 355 mM^{-1} s^{-1}/nanoprobe, which benefits to generate detectable MR signal even nanoprobe concentration is low in brain tissues.

In vitro competition studies clearly indicated the dominated role of LRP receptor played in the cellular uptake of **Den-RGD-Angio**. Actually, the maximum cellular uptake velocity of **Den-RGD-Angio** performed in the beginning of treatment can be explained by the overwhelming ligand/receptor association that is much faster than the active internalization. The highest cellular uptake rate of **Den-RGD-Angio** in the whole incubation period presumably results from synergistic receptor targeting effect of angiopep-2 and c[RGDyK] peptides.

BBB permeability of **Den-RGD-Angio** was unambiguously verified by *in vivo* MR/optical imaging, *ex vivo* optical imaging as well as microscopic imaging studies. The role of LRP receptor mediated transcytosis played in the intracerebral delivery is obvious because MR/NIR fluorescence signal enhancements in cortex were only observed after the injection of nanoprobes modified with angiopep-2 ligand. Interestingly, even angiopep-2 densities on **Den-RGD-Angio** and **Den-Angio** were the same, **Den-RGD-Angio** showed a higher BBB traverse efficiency compared to **Den-Angio**. Milner et al reported the presence of $\alpha_V\beta_3$ integrin in the BCECs.[43] The synergistic targeting effect of **Den-RGD-Angio** found in cell culture studies may also increase its local concentration in BCECs, which further

accelerates its BBB traverse efficiency. Due to the high tissue penetration capability of NIR fluorescence, the intracerebral delivery of nanoprobe was detected by NIR optical imaging as early as 2 h PI, which provided a convenient and sensitive way to dynamically track the intracerebral delivery of nanoprobe.

Both MR and optical imaging demonstrated the intratumoral delivery of all four nanoprobes *in vivo*. Due to the EPR effect, all nanoprobes can enter the tumor by extravasating the impaired BBB. However, compared to the controls, **Den-RGD-Angio** not only offered the highest T/N ratio, but also precisely delineated the tumor boundary. The perfect tumor boundary correlation between the *in vivo* MR image and the *ex vivo* histological images indicates the feasibility of this nanoprobe to pre-surgerically locate the brain tumor. Recently, Zhang et al. reported an iron oxide nanoparticle based T2-weight MR probe modified with chlorotoxin (CTX) as the targeting ligand.[44] Even this nanoprobe successfully visualized the transgenic ND2:SmoA1 brain tumor *in vivo*, the neoplastic tissue cannot be precisely defined until 48 h PI due to the slow extravasation rate of the nanoprobe. Furthermore, the “negative contrast” signal induced by the iron oxide particles may mislead the clinical diagnosis because endogenous tissues such as necrosis, calcification, hemorrhage or metal deposition are also presented as “hyphointense areas” in MRI.[45] Therefore, our nanoprobe with fast intratumoral delivery rate and “positive” signal enhancement in neoplastic tissues is more desirable to the radiologist. Furthermore, due to the extremely high T/N ratio of **Den-RGD-Angio** performed in the *ex vivo* optical imaging studies, this nanoprobe holds promise in the real-time optical imaging guided surgery to

completely remove the neoplastic tissues with the minimized impairments to the surrounding normal neurological tissues.

As indicated in the microscopic immunofluorescence studies, high colocalization coefficients between **Den-RGD-Angio** and the LRP receptor as well as β_3 integrin at 2 h PI indicated the involvement of both receptors in the targeted delivery of nanoprobe. Additionally, in contrast to the location of **Den-PEG** at the tumor periphery, **Den-RGD-Angio** was distributed in the whole tumor area and internalized into cytoplasm. Above experimental results support the assumed two-order targeted imaging strategy. At 24 h PI, remarkably reduced co localization coefficients may be interpreted by the "receptor occupation effect",[46] in which the receptors on cancer cells were preoccupied by the nanoprobe and hardly to be immunostainned by corresponding antibodies. Compared to the **Den-PEG**, the average cellular fluorescence intensities of **Den-RGD-Angio** and **Den-Angio** in normal brain tissues increased to 67−75%, which is a solid evidence of the LRP-mediated transcytosis *in vivo*. Overall, the combination of EPR effect, up-regulated BBB permeability, and the two-order targeting strategy jointly contributes to the high T/N ratio of **Den-RGD-Angio**.

Conclusion

Overall, this work developed a novel two-order targeted imaging strategy that successfully visualized orthotropic brain tumor xenograft with high sensitivity and target to background signal ratio *in vivo*. This multimodal nanoprobe not only demonstrated the feasibility to pre-operatively localize brain tumors by both MRI and optical imaging, but also provided a

potential solution to delineate the malignant tumor with uncompromised BBB. Additionally, due to its extraordinarily high T/N ratio performed under the *ex vivo* condition, this nanoprobe holds a promise in NIR optical image-guided brain tumor resection during the surgery.

MATERIALS AND METHODS

Materials. All chemicals were analytical grade from Aladdin Reagent (Shanghai, China) unless otherwise specified. PAMAM G5 dendrimer (77.35 mg/mL in MeOH) was purchased from DendritechInc (Midland, USA). Rhodamine-NHS, Cy5.5-NHS and SPDP were from Thermofisher Scientific (NY , USA). Fetal bovine serum (FBS), penicillin, streptomycin, Alexa Fluo 488 or horseradish peroxidase (HRP) labeled goat anti-rabbit secondary antibodies were from Invitrogen (Carlsbad, USA). Rabbit anti-mouse/human β-actin, β_3 integrin and LRP-1 primary antibodies were from Epitomics (Burlingame, USA). Malemide-PEG^{2k}-NHS and PEG^{2K}-NHS were from JenKem Technology (Beijing, China). DOTA-NHS was prepared according to previous report.[47] $Gd_2(CO_3)_3$, DAPI, Bolton-Hunter reagent and MTT were purchased from Sigma-Aldrich (St. Louis, USA). Isoflurane was from Baxter Healthcare Corporation (New Providence, USA).

Western Blot Studies. Approximately 3 × 10^6 cells at 80% confluence were homogenized with lysis buffer containing protease inhibitors. 80 μg total protein determined by a modified Lowry assay (Bio-Rad) were resolved on a 7% SDS-PAGE. The gels were transferred to polyvinylidenedifluoride membranes, blocked, cut and incubated with β-actin (1:50000) or β_3 integrin (1:1000) or LRP-1 (1:20000) primary antibodies. The membrane

was incubated with HRP labeled goat anti-rabbit secondary antibody (1:2000) and visualized by using the Supersignal WestPico chemiluminescent substrate kit (Pierce Biotechnology, USA).

Cell Culture Studies. U87MG, PC3, MDA-MB-231 and BCECs (ATCC) were cultured as recommended by the supplier.

Confocal Fluorescence Microscopic Imaging. Fluorescence microscopic images were collected on a Zeiss LSM 510 META confocal laser scanning microscope (Carl Zeiss, Germany) by using a 40× oil immersion lens. DAPI was excited with a 405 nm laser and the emission was detected with a photomultiplier by a 420–480 nm band-pass filter. Alexa Flour 488 was excited with a 495 nm laser and emission was detected by a second photomultiplier using a 505–550 nm band-pass filter. Rhodamine was excited with a 543 nm laser and the emission was detected by a third photomultiplier using a 560 nm band-pass filter.

Flow cytometry. U87MG cells with 80% confluence were treated with 1.0 μM nanoprobe in which the rhodamine was replaced by fluorescein. At the end of incubation, the cells were washed, centrifuged, fixed and analyzed by BD FACSAria (BD Biosciences，USA) equipped with a 488 nm Ar-Ion laser.

.

Tumor Implantation. All animal experiments were carried out in accordance with guidelines approved by the ethics committee of Fudan University, Shanghai, China.

U87MG cells (5.0×10^5) were inoculated into the right striatum (1.8 mm lateral, 0.6 mm anterior to the bregma and 3.0 mm of depth) of male Balb/c nude mice by using a stereotactic fixation device with mouse adaptor. The intracranial tumors with a diameter of 0.5−1.0 mm were ready for imaging after inoculation for 14−18 days.

***In vivo* MRI Studies.** *In vivo* MR imaging was carried out on a Biospec 47/30 MRI scanner (Bruker Inc., MA). The mice were anesthetized with isoflurane and their heads were placed into a home-built solenoid coil. Mouse respiration was continuously monitored by a Bruke PhysioGard system. Dynamic T1-weighted images of the brain were collected before and after bolus administration of nanoprobe with a dose of 0.05 mmol/kg [Gd^{3+}] in a 0.25 mL PBS *via i.v.*. Coronal images of the brain sections with 1.0 mm thickness were acquired with a spin-echo pulse sequence [field of view (FOV): 2 cm × 2 cm, matrix size: 128 × 128, TR = 300 ms, TE = 11 ms, and number of average (NOV) = 8]. The intensity enhancement (IE) of region of interest (ROI) at time point t is expressed by IE = (RI(t) – RI(0))/RI(0) × 100%, where RI(t) and RI(0) correspond to the normalized signal intensities measured at time point t and pre-injection.

***In vivo* and *ex vivo* Optical Imaging Studies.** *O*ptical images were acquired on a Kodark Multispectral Imaging System equipped with a 750 nm excitation filter and a 800 nm emission band pass filter set. All X-ray images were acquired by using 0.2 s exposure time and NIR fluorescence images were acquired using 0.5 s exposure time (FOV = 6.4 or 12.8 cm; f/stop, 4; bin, high resolution). The fluorescence intensities were quantified by ImageJ

software (NIH).

Bio-distribution. Nanoprobes were radiolabeled with ^{125}I isotope by using the Bolton-Hunter reagent (Pierce Biotech., USA). U87MG tumor bearing mice were randomly divided into four groups and injected with [^{125}I] labeled nanoprobe (3.0×10^5 Bq/mouse) *via i.v.*. The mice were sacrificed at 24 h PI and perfused with saline. Selected organs were excised, weighted and the radioactivity was counted with an automatic γ-counter. The biodistribution data were presented as percentage of the injected dose per gram (%ID/g).

Autoradiography Studies. After bio-distribution studies, mouse brains were excised, cryo-sectioned with a thickness of 20 μm. The autoradiogram images were collected by a cyclone pulse storage phosphor system (Perkin Elmer, USA) with an exposure time of 24 h. The white light pictures of these brain sections were taken by a Leica MZ75 (Leica Inc., Germany) high-performance stereomicroscope equipped with 2.5 X plano objective.

Histological and Immunohistological Staining. Tumor bearing brains were fixed, dehydrated, and sectioned at least 15 sections per brain with a thickness of 20 μm. The sections from each brain were divided for three groups. Group one were stained with hematoxylin and eosin (H&E); group two were stained with β_3 integrin primary antibody followed the fluorophore labeled secondary antibody and DAPI at last; group three were stained by LRP-1 primary antibody followed the secondary antibody and DAPI at last.

Statistical Analysis. Values presents mean ± SD when the sample number is above 3

(n > 3). Statistical differences were evaluated with two tailed corrected Student's *t* test (SPSS, IBM); $P < 0.05$ was considered significant. Values are presented as mean and data range (from minimum value to maximum value) when the sample number is 3 (n = 3).

Acknowledgements.

This work was supported by the National Basic Research Program of China (973 program, 2011CB910404), the National Natural Science Foundation of China (No. 30900353, 81171384, 20975027), and Program for New Century Excellent Talents in University Award (NCET-08-0131). We thank the helpful discussion with Prof. X. Y. Feng and Prof. C. Jiang.

Table and Figures

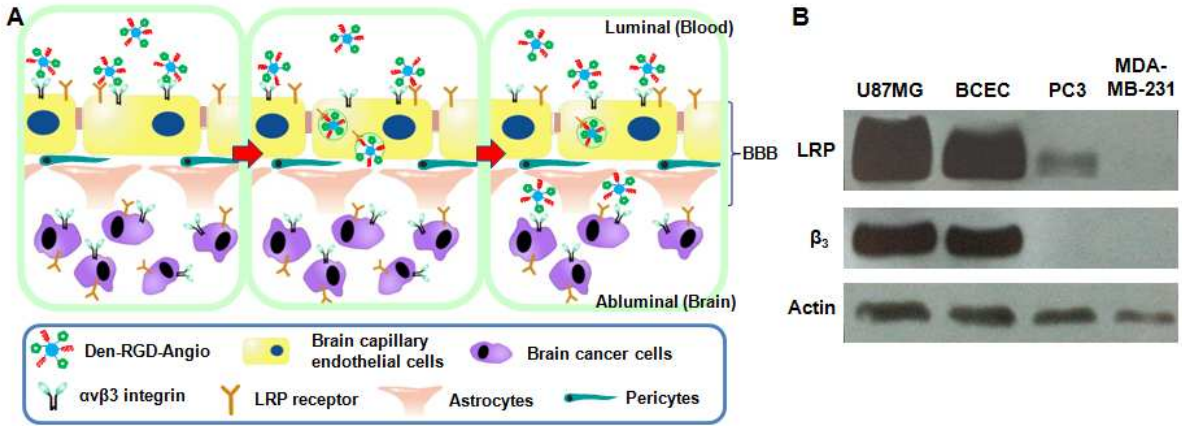

Figure 1. Design of the two-order targeted nanoprobe for brain tumor imaging. (A) Overview of two-order targeted brain tumor imaging strategy. The nanoprobe firstly targets the $\alpha_V\beta_3$ integrin on tumor vasculatures. After binding with nearby LRP receptors, the nanoprobe traverses BBB *via* LRP receptor-mediated transcytosis and finally targets tumor cells directly. (B) Western blot shows the over-expression of both $\alpha_V\beta_3$ integrin and LRP receptor in human gliomblastoma U87MG cancer cells and BCECs.

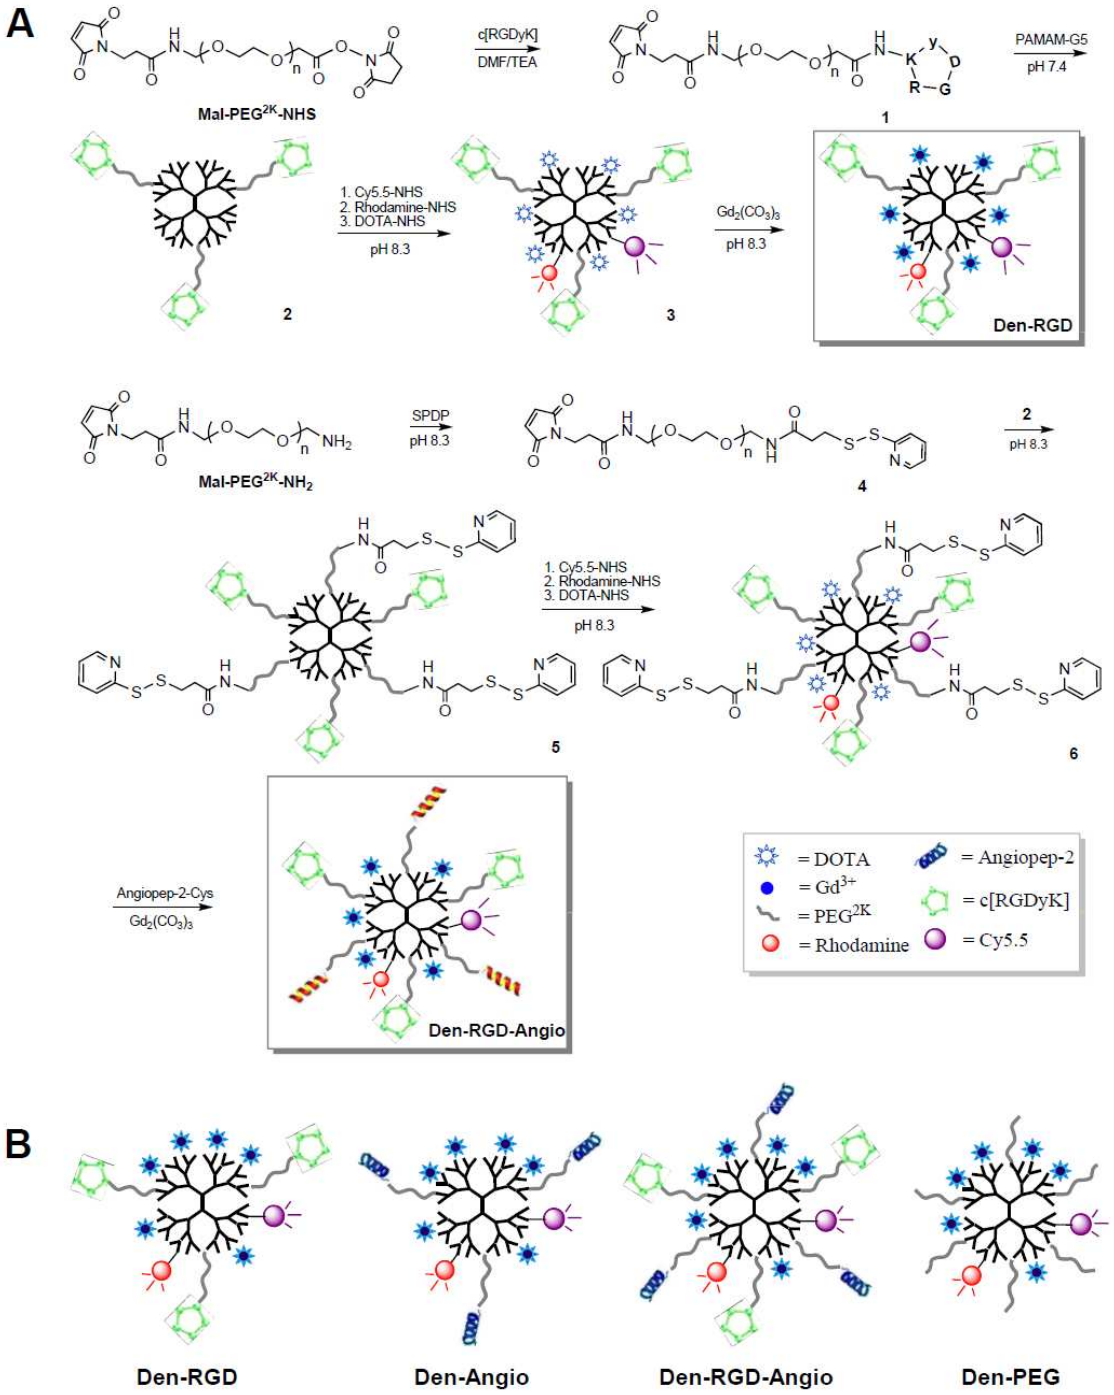

Figure 2. (A) Synthetic steps of nanoprobes **Den-RGD** and **Den-RGD-Angio**. (B) Schematics of the aiming and control nanoprobes.

Table 1. Physical parameters of the nanoprobes

Nanoprobe	d (nm)[a]	PDI[a]	ζ (mV)[a]	Gd%[b]	r_{1p} ($mM^{-1}s^{-1}$)[c]	MW (kDa)[d]
Den-PEG	11.5	0.258	16.7	12.5	7.4 ± 0.4	82
Den-RGD	13.2	0.193	10.4	9.6	7.1 ± 0.3	81
Den-Angio	13.3	0.287	11.6	9.4	6.9 ± 0.4	83
Den-RGD-Angio	15.6	0.224	8.6	9.6	7.1 ± 0.2	91
G5 Dendrimer	7.1	0.157	21.5	n.d.	n.d.	30

[a] Diameters (d), polydispersity index (PDI) and Zeta potentials (ζ) were measured by dynamic light scattering (DLS). [b] Gadolinium concentrations (Gd%) were measured by inductively coupled plasma atomic emission spectroscopy (ICP-AES). [c] T1-weighted relaxivities (r_{1p}) were determined on 4.7 T MRI at 25 ºC. [d] Molecular weights (MW) were measured by MALDI-TOF MS.

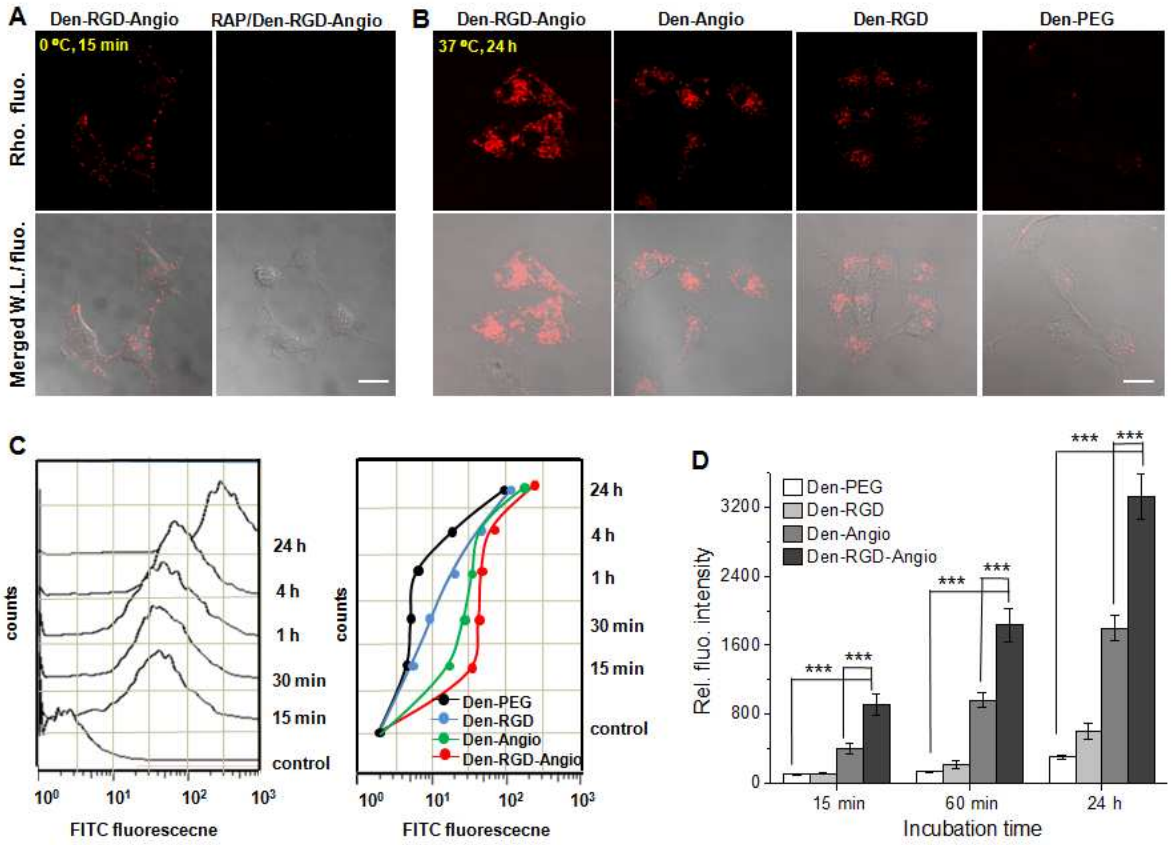

Figure 3. Den-RGD-Angio demonstrated a higher cellular uptake efficacy than the control nanoprobes in U87MG cells. (A) Confocal fluorescence microscropic images of the live cells treated with 1.0 μM **Den-RGD-Angio** for 15 min or pre-treated with 2.0 μM RAP for 30 min followed the nanoprobe treatment. Above experiments were conducted at 4 ºC. Rhodamine fluorescence was displayed in red. (B) Microscopic fluorescence images of the live cells treated with 1.0 μM selected nanoprobe for 24 h at 37 ºC. Scale bar, 15 *μ*m. (C) Time-dependent flow cytometries of the cells treated with **Den-RGD-Angio** (1.0 μM, left panel) and time-dependent cellular fluorescence intensity curves after treatment of nanoprobe (1.0 μM, right panel). (D) Mean cellular fluorescence intensities after nanoprobe treatment for 15 min, 1 h and 24 h at 37 ºC. The values represent mean ± SD (n = 4). (***) $P < 0.001$.

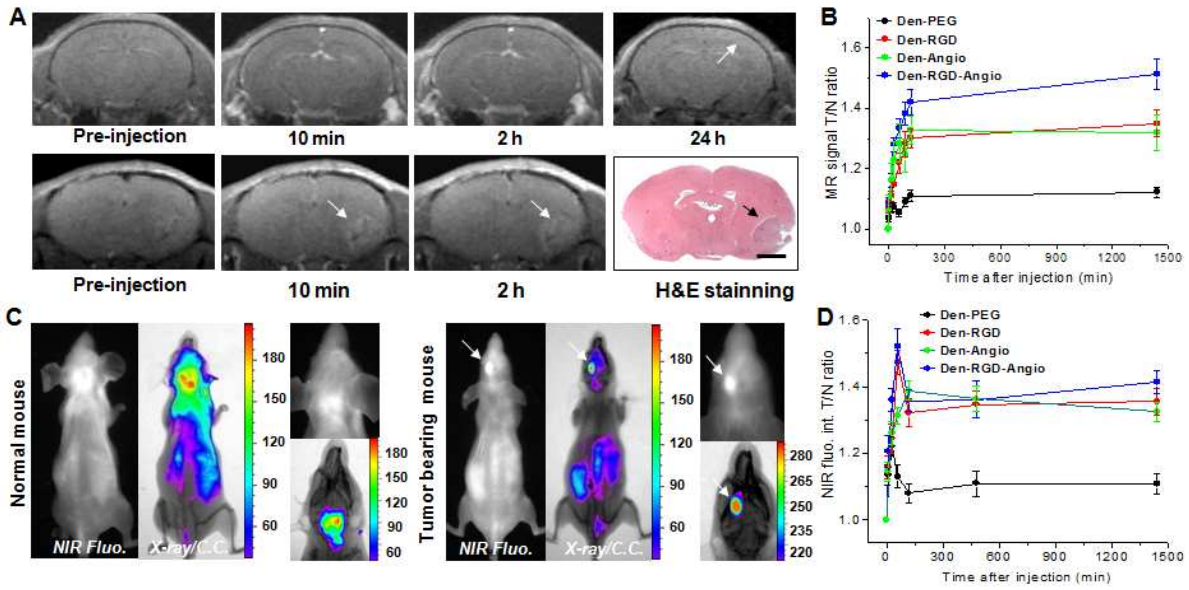

Figure 4. Den-RGD-Angio demonstrated high BBB permeability and T/N ratio *in vivo*. (A) Representative T1-weighted MR images of normal mouse brain (upper panel, arrow points to the cortex) and tumor bearing brain (lower panel, arrows point to the tumor) before and at selected time PI of **Den-RGD-Angio** (0.05 mmol/kg [Gd^{3+}], *i.v.*). Histological H&E staining verified the tumor boundary in MRI (Bar, 2.0 mm). (B) *In vivo* time-dependent MR signal associated T/N ratio before and PI of nanoprobe (n = 4). Points present mean values and bars present the maximum and minimum values (data range). (C) Representative NIR fluo. and X-ray/color coded NIR fluo. images of the normal mouse (left panel) and brain tumor bearing mouse (right panel) at 24 h PI of **Den-RGD-Angio** (5.0 nmol/mouse based on dendrimer). (D) *In vivo* time-dependent NIR fluorescence T/N ratio (n = 3). Points present mean values and bars present the data range.

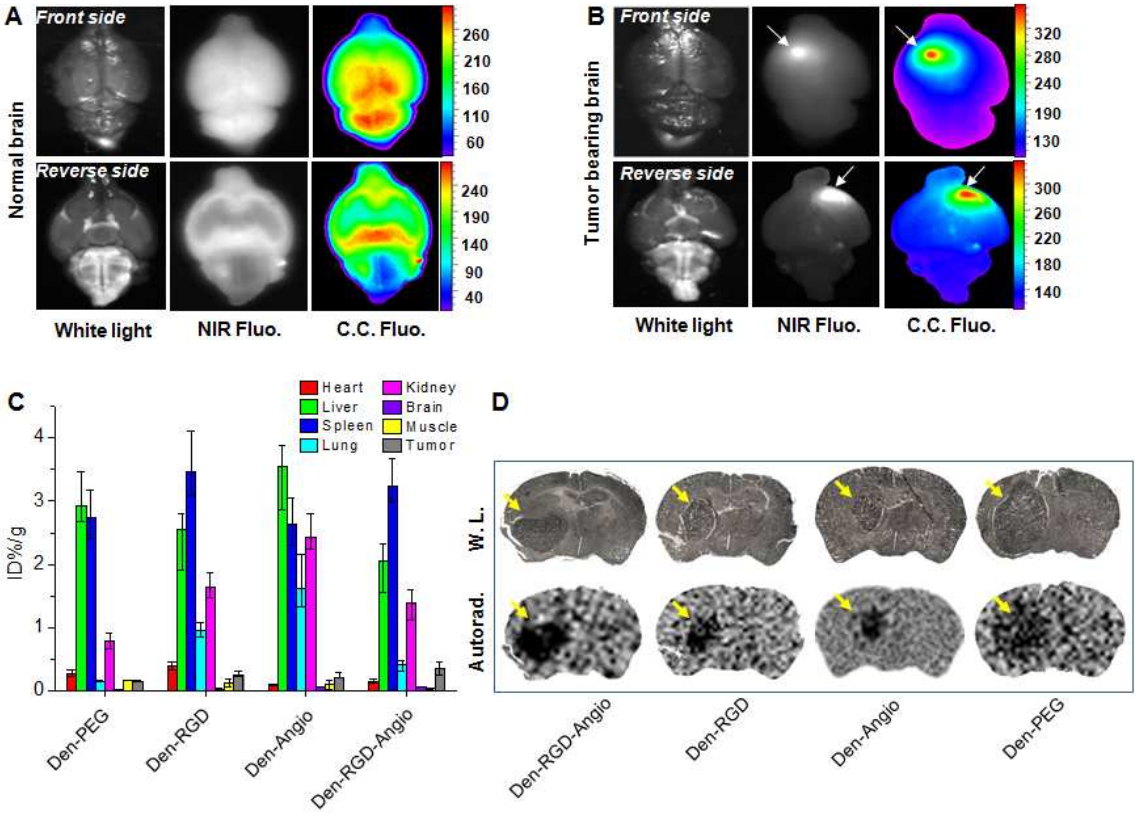

Figure 5. Bio-distribution and *ex vivo* imaging studies verified the high T/N ratio of **Den-RGD-Angio**. Representative white light, NIR fluorescence and color coded fluorescence images of normal mouse brain (A) and tumor bearing mouse brain (B) at 24 h PI of **Den-RGD-Angio**. Arrow points to the tumor. (C) Biodistribution of nanoprobe labeled with ^{125}I radioactive isotope (1.8×10^5 Bq/mouse) in tumor bearing mice (n = 3) at 24 h PI. Columns present mean values and bars present the data range. (D) Representative white light microscopic images and autoradiographic images of tumor bearing brain sections at 24 h PI of the radioactive nanoprobe. Arrows point to the tumors.

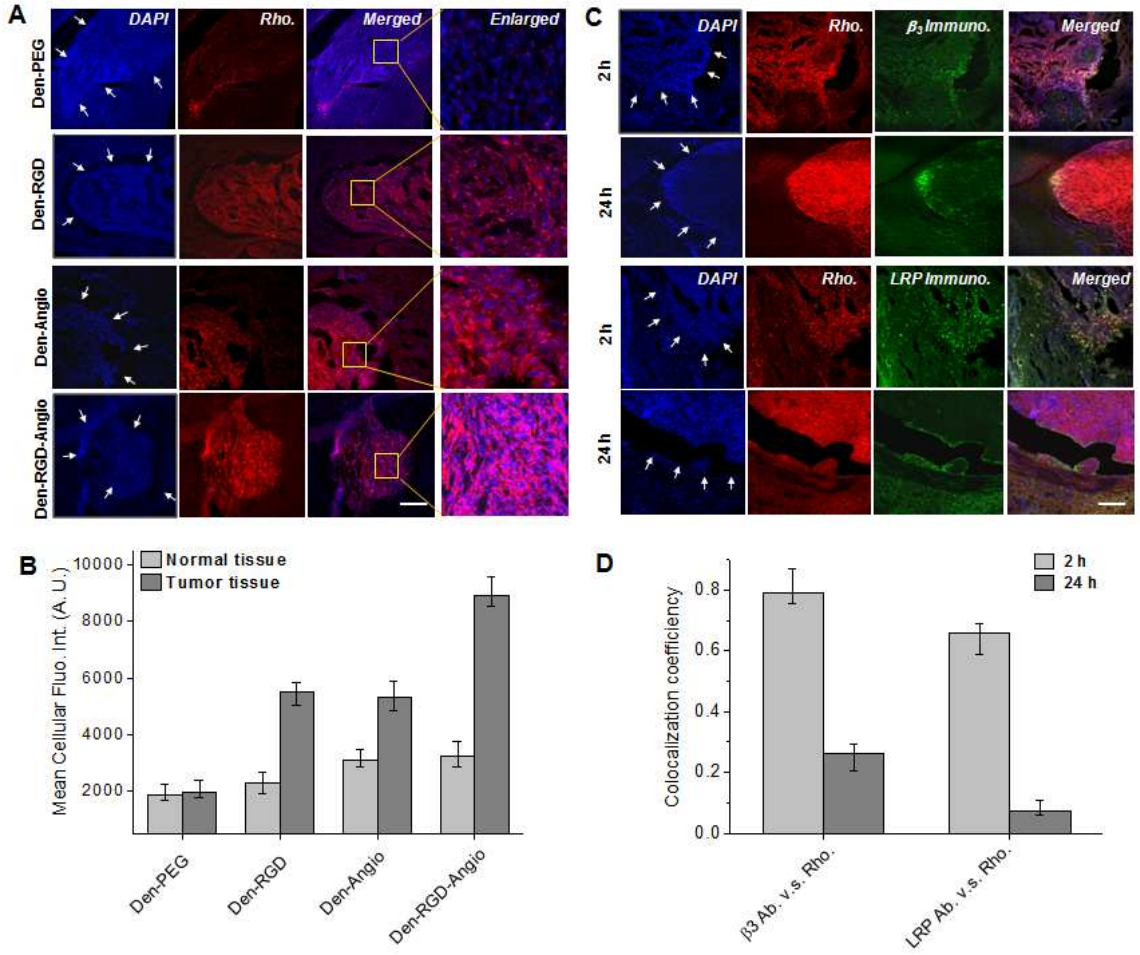

Figure 6. $\alpha_V\beta_3$ integrin and LRP receptor are involved in the two-order targeted imaging strategy. (A) Representative confocal microscopic fluorescence images of tumor bearing brain sections at 24 h PI of nanoprobe (5.0 nmol/mouse). Rhodamine in nanoprobe was displayed in red and the nuclei stained with DAPI were displayed in blue. Tumor boundary was indicated by the arrows. Scale bar, 200 μm. (B) Intracellular fluorescence intensity at 24 h PI of the nanoprobe. The data were quantified by normalizing the gross rhodamine fluorescence with the number of nuclear in the indicated areas. Columns present mean values and bars present the data range. (Randomly selected 15 images analyzed from 3 tumors after a nanoprobe injection). (C) Representative microscopic fluorescence images of tissue sections immunohistologically stained with β_3 integrin antibody (upper panel) and LRP antibody (lower panel) at 2 and 24 h PI of **Den-RGD-Angio**. The immunofluorescence was displayed in green. Scale bar, 200 μm. (D) Colocalization coefficients between the nanoprobe fluorescence and the immunofluorescence in the tumor at 2 and 24 h PI of **Den-RGD-Angio**. (Randomly selected 18 images analyzed from 3 tumors after a nanoprobe injection).
